

How to open our sln in both debug and release.

Step1.)

Go here <https://cmake.org/download/> and install cmake

And also go here <https://git-scm.com/downloads> and download GIT

Step2.)

DI the windows x64 ver for cmake, same as with GIT

Latest Release (4.1.2)

The release was packaged with CPack which is included as part of the release. The .sh files are self extracting gzipped tar files. To install a .sh file, run it with /bin/sh and follow the directions. The OS-machine.tar.gz files are gzipped tar files of the install tree. The OS-machine.tar.Z files are compressed tar files of the install tree. The tar file distributions can be untared in any directory. They are prefixed by the version of CMake. For example, the linux-x86_64 tar file is all under the directory cmake-linux-x86_64. This prefix can be removed as long as the share, bin, man and doc directories are moved relative to each other. To build the source distributions, unpack them with zip or tar and follow the instructions in README.rst at the top of the source tree. See also the [CMake 4.1 Release Notes](#).

Step3.)

Run the windows 64x installer for both.

Step4.)

After downloading cmake and GIT, open our custom engine folder and you should see this. Run the run.bat to build the debug and release executables with cmake. Run clean.bat to remove the build folder and out files.

IMPORTANT!

When opening the sln, right click sln explorer, go to properties

And set startup proj to LetsEatMonsters

If you want to enable LV4 warnings, go under TheStove, properties, and

Under C/C++, change warning to lv4
